

"Connecting Two and Four Dimensional Physics
in a Supersymmetric World"

Heng-Yu Chen

(Physics, National Taiwan University)

Based on 1104 3021, 1205 4230 with Nick Dorey, Sungjay Lee,
Peng Zhao (Cambridge) and Tim Hollowood (Swansea)

+ 1303 4237 with Annamaria Sinkovics

Two dimensional σ -model have served as a **powerful paradigm** in helping us understanding **Four dimensional non-Abelian theories**

They are known to share many important features

- Asymptotic Freedom
- Generation of mass gap
- Confinement
- Chiral Symmetry Breaking
- Large N -expansion
- Instantons
- Anomalies / Current Algebra

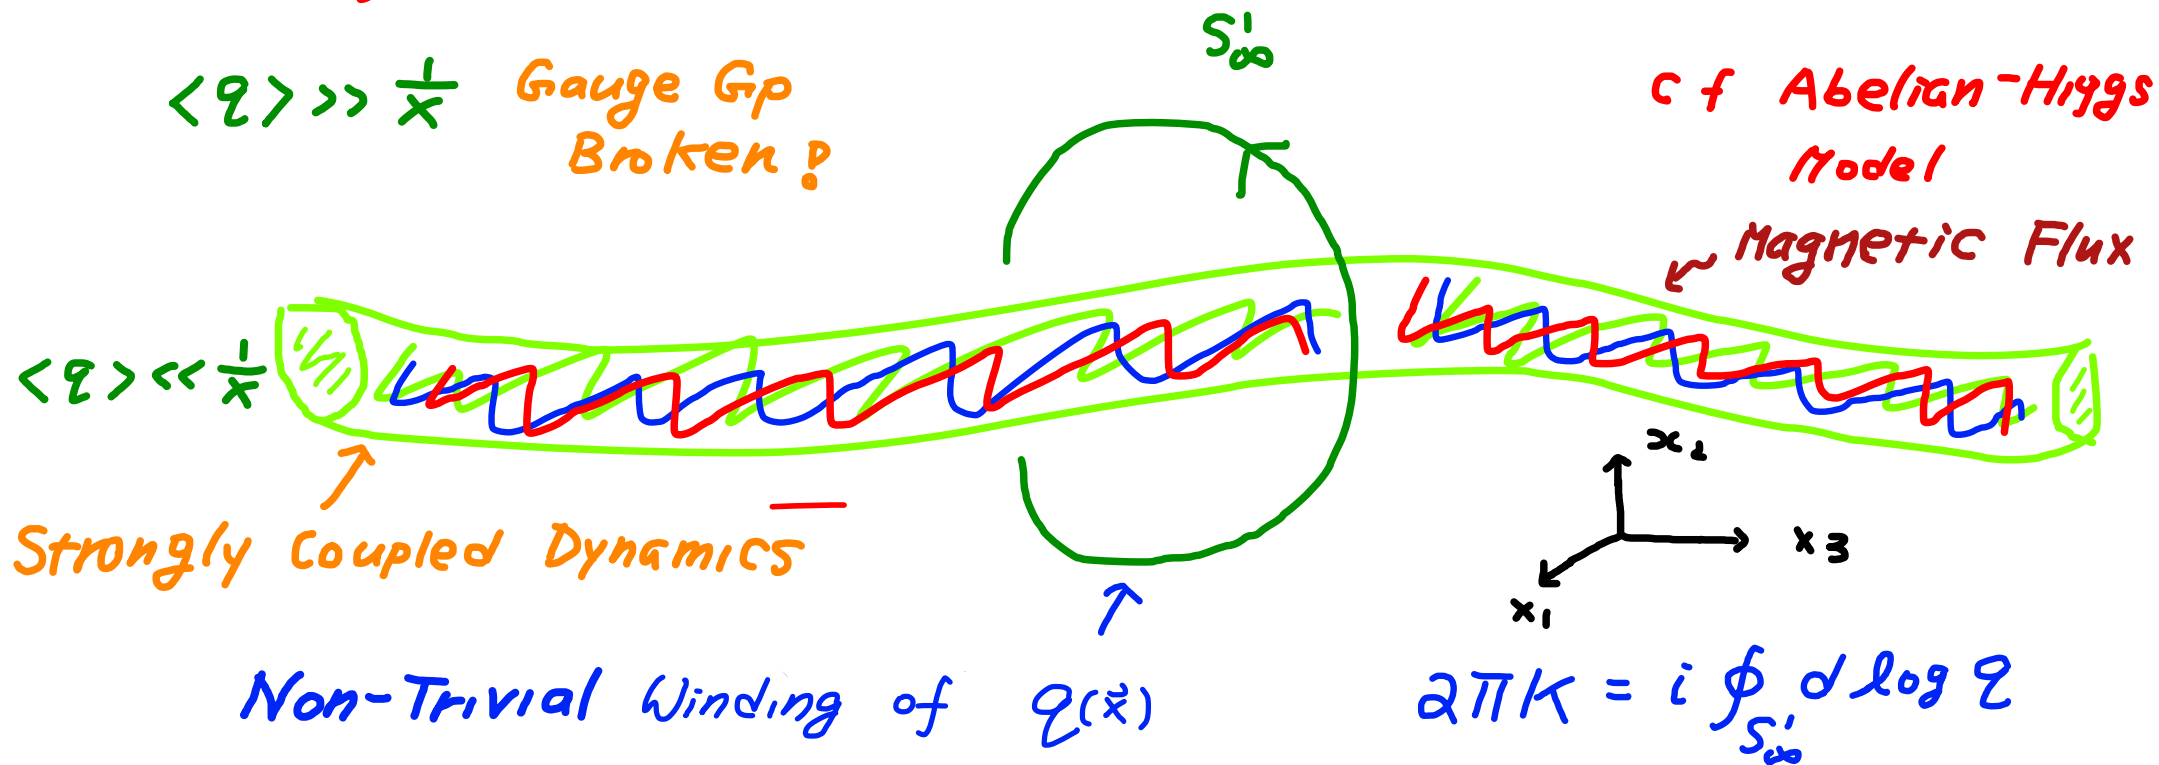

Gross-Neveu, Witten,
D'Adda-Luscher - Di Vecchia etc

But 2d σ -models are "a bit nicer", exhibiting striking features, such as **Bosonization, infinite Conserved Charges**, important for us
"Connection with Integrable Systems"

The qualitative connections between 2 dim σ -Models and 4 dim Non-Abelian Gauge Theories can be made "Quantitative"

"Solitonic Vortex Strings Precisely Provides Such Connection"

The Basic Idea is, we consider 4 dim Non-Abelian Theory with some quarks q , we go to "Higgs Phase" $\langle q \rangle \neq 0$ (Scalar)

More concretely, we consider 4dim Theory with $U(N_c)$ Gauge Gp and N_f flavors (+ SUSY generalization) ($U(1)$ Abelian Higgs)

$$\mathcal{L} = \frac{1}{4e^2} \text{Tr} F_{\mu\nu} F^{\mu\nu} + \sum_{i=1}^{N_f} |Dq_i|^2 - \frac{e^2}{2} \text{Tr} \left(\sum_{i=1}^{N_f} |q_i|^2 - v^2 \right)^2$$

↑ FI-Parameter

(+ Fermions for SUSY)

$$N_c = N_f$$

"Color-Flavor Locking"

$$q_i^\alpha \quad \alpha = 1, \dots, N_c, \quad i = 1, \dots, N_f$$

Vacuum $\langle q_i^\alpha \rangle = v \delta_i^\alpha, \quad U(N_c) \times SU(N_f) \rightarrow S[U(N_c) \times U(N_f - N_c)]$

Mass Gap $m_q = m_g \sim e v$

Overall $U(1)$ is broken by the vev

→ Solitonic Vortex String Solution exists, labeled by

$$\pi_1 \left(\frac{U(N_c) \times SU(N_f)}{S[U(N_c) \times U(N_f - N_c)]} \right) = \mathbb{Z} \quad \leftarrow \text{Vortex Number}$$

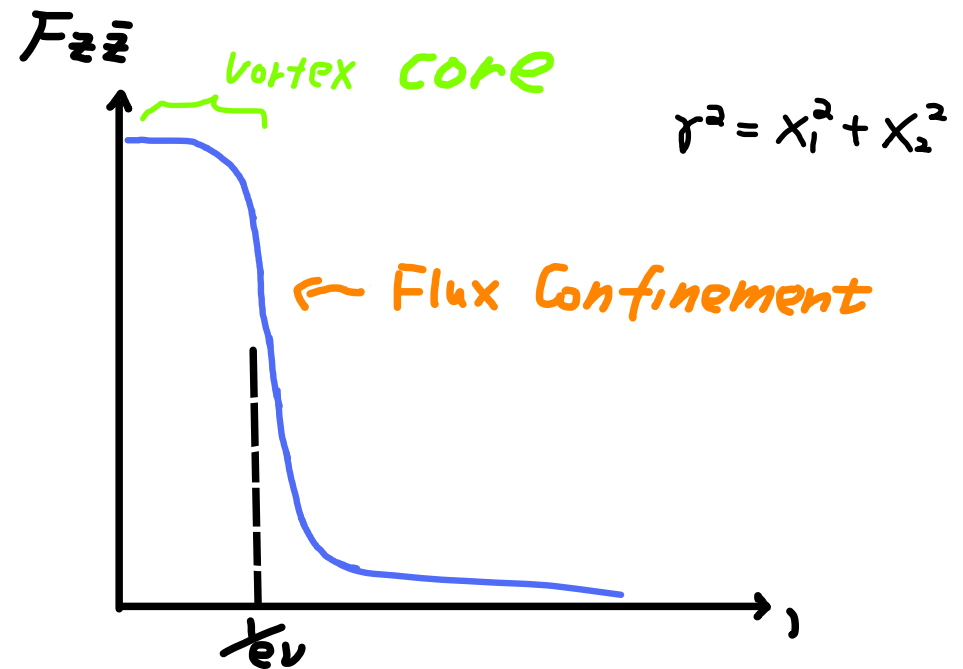

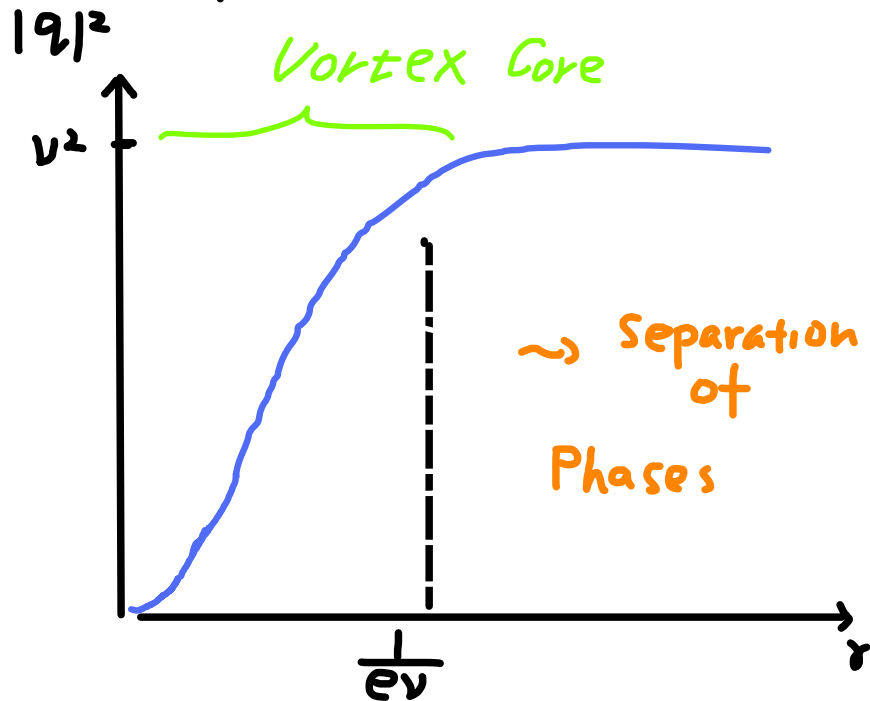

To find vortex solution, use Bogomolny Completing the square trick

Vortex Equation
(in x^0-x^3)

$$(F_{z\bar{z}})^\alpha{}_\beta = e^2 \left(\sum_{l=1}^{N_f} \varrho_l^\alpha \varrho_{l,\beta}^+ - v^2 \delta^\alpha{}_\beta \right)$$

$$D_z \varrho = 0 \quad (z = x_1 + ix_2)$$

The analytic solutions **unknown**, but it can be solved **numerically**

The vortex world volume dynamics "Probes" the 4 dim **Strong Coupling Dynamics**!
(Two Dimensional)

The low energy vortex dynamics is given by "Moduli Space Approximation"
(Manton)

Moduli space metric g_{IJ} can be obtained from

$$g_{IJ} = \text{Tr} \int d^2z \frac{1}{e^2} \delta_I A_z \delta_J A_{\bar{z}} + \sum_{i=1}^{N_f} \delta_I \varphi_i^\alpha \delta_J \varphi_i^{\dagger\alpha} + h.c$$

$(\delta_I A, \delta \varphi)$ are so-called "Zero Modes" (Bosonic) (Linearized Fluctuations)

We can also identify moduli space by considering different ways of embedding vortex solutions For $k=1, N_f = N_c$

$$\mathcal{M}_{1, N_c, N_c} = \frac{SU(N_c)_d}{U(1) \times SU(N_c-1)} \cong \mathbb{C}P^{N_c-1}$$

Widely Studied

"The low energy dynamics is given by 2 dim σ -model with target space being $\mathbb{C}P^{N_c-1}$ The size/Kähler is proportional to $\frac{1}{e^2}$ "

More general configuration, arbitrary k, N_c and N_f etc we can

obtain the moduli space $\mathcal{M}_{k, N_c, N_f}$ via D-brane construction

(Hanany-Tong, Dorey, Hollowood etc)

If the 4 dim Gauge Theory also has "fermions", they also descend into 2 dim Vortex World Volume as "fermionic zero modes"
⇒ Combined with "bosonic zero modes", we can have "Supersymmetry"
(in 2 dim)

- Here we are most interested in $N=(2,2)$ Supersymmetric $D=2$ models
So far the discussion is classical, for their "quantum dynamics",
it's more powerful to rewrite them as "Gauge Theories" (Vitten),
Sometimes referred as "Gauged Linear Sigma Model (GLSM)"
- Various Aspects of $N=(2,2)$ GLSM have been studied,
(Dorey, Shifman-Yung, Hanany-Tong), in particular the Soliton Spectrum bears
close resemblance to the BPS Soliton Spectrum of famous
"4 dim $N=2$ Supersymmetric Gauge Theories (Seiberg-Witten)"

Coupling

The Particular $N=(2,2)$ GLSM we focus on has $G=U(K)$ \mathfrak{g}

+ N_c fundamental Chiral Multiplets of (twisted) masses $(M_1, M_2, \dots, M_{N_c})$,

+ N_c anti-fundamental Chiral Multiplets of (twisted) masses $(\tilde{M}_1, \tilde{M}_2, \dots, \tilde{M}_{N_c})$,

+ 1 adjoint Chiral Multiplet of (twisted) mass ϵ

We also add Fayet-Iliopoulos term (FI) r + $2d$ theta angle Θ_{2d}

and combine to form $\tau = ir + \frac{\Theta_{2d}}{2\pi} \rightsquigarrow$ Coupled through Field Strength

Interesting low energy dynamics or "quantum vacua" is governed

by an "Exact twisted superpotential $W_{\text{eff}}(\lambda)$ " ($\lambda \sim$ twisted chiral mult)

(Witten, Cecotti-Vafa)

$$\mathcal{L}_{\text{eff}} = \int d^3\theta \underbrace{W_{\text{eff}}(\lambda)}_{\text{Potential}} + \int d^3\bar{\theta} \overline{W_{\text{eff}}(\bar{\lambda})} + \int d^4\theta \underbrace{K(\lambda, \bar{\lambda})}_{\text{kinetic terms}}$$

$W_{\text{eff}}(\lambda) \sim$ obtained from integrating out massive matters

Explicit Form of $W_{\text{eff}}(\Sigma)$ is

"Generating Function for Quantum Integrable System"

$$W_{\text{eff}}(\lambda) = 2\pi i \tau \sum_{j=1}^K \lambda_j - \epsilon \sum_{j=1}^K \sum_{\ell=1}^{N_c} f\left(\frac{\lambda_j - M_\ell}{\epsilon}\right) + \epsilon \sum_{j=1}^K \sum_{\ell=1}^{N_c} f\left(\frac{\lambda_j - \tilde{M}_\ell}{\epsilon}\right) + \sum_{i,j=1}^K f\left(\frac{\lambda_i - \lambda_j - \epsilon}{\epsilon}\right) \quad (f(x) = x(\log x - 1))$$

The minima / Vacuum is given by $\frac{\partial W_{\text{eff}}(\lambda)}{\partial \lambda} = 0$, explicitly

$$\prod_{\ell=1}^{N_c} \frac{\lambda_j - M_\ell}{\lambda_j - \tilde{M}_\ell} = q \prod_{k \neq j}^K \frac{\lambda_j - \lambda_k - \epsilon}{\lambda_j - \lambda_k + \epsilon}, \quad q = e^{2\pi i \tau} (-1)^{K+1}$$

This looks strikingly close to "Bethe Ansatz Equation" to "inhomogeneous twisted XXX Spin Chain"! (indeed the case after identifying parameters)

(Obtained from Algebraic Bethe Ansatz)

This is an example that "Vacuum" of gauge theory is encoded in a "Quantum Integrable System"

We have seen similar "moduli Space / Integrable System Connection",
from the "Coulomb branch of 4dim $N=2$ SUSY gauge theories" (Seiberg
-Witten)

In fact, the quantum spin chain we just met, its classical cousin
has already made appearance in the following 4dim Gauge Theory

" $N=2$ Super - QCD"

We have $U(N_c)$ **Vector Multiplet** + N_c "fundamental hypermultiplets" of
masses $(m_1, m_2, \dots, m_{N_c})$
 $\setminus N_c$ "Anti-fundamental hypermultiplets" of
masses $(\tilde{m}_1, \tilde{m}_2, \dots, \tilde{m}_{N_c})$

The theory also has **Complex gauge coupling** $\tau = \frac{4\pi i}{g_{4D}^2} + \frac{\Theta}{2\pi}$

The moduli Space has "Coulomb" and "Higgs Branch"

Higgs Branch $\langle \text{squark} \rangle \neq 0$, protected from quantum corrections by
non-renormalizations

Coulomb Branch

$$[\phi, \phi^\dagger]^2 = 0 \quad (\phi \sim \text{Adjoint Scalar in Vector Multiplet})$$

$$\langle \phi \rangle \sim \text{diag}(\phi_1, \phi_2, \dots, \phi_{N_c}), \quad U(N_c) \rightarrow \underbrace{U(1)^{N_c}}_{\text{Generalized EM}} \quad (\Lambda \ll \langle \phi \rangle)$$

- Classical Coulomb metric can be "quantum corrected", but only one-loop perturbatively, it can further receive non-perturbative instanton corrections (Difficult to compute order by order)
- The famous work of Seiberg and Witten, determined exactly the quantum Coulomb branch metric / effective coupling
- They do so by relating the system to an auxiliary algebraic curve

The gauge coupling τ is the "Complex Structure" of Σ_{SW} or the "ratio" between A & B cycles

The integrals of λ_{SW} over A & B cycles play the role of "Electric" and "Magnetic" Coordinates in low energy SQED (Emerging KE)

$$a_I(u) = \oint_{\alpha_I} \lambda_{SW}(u) \quad , \quad a_I^D(u) = \oint_{\beta_I} \lambda_{SW}(u)$$

Related by

$$\checkmark \quad \rightarrow \quad \checkmark$$

$$\underline{\underline{F(\vec{a}, \vec{m})}}$$

"Prepotential"

($u \sim$ moduli on the curve,

Coming from Weyl invariant combination of $\langle \phi \rangle$)

Example

"Pure $N=2$ $SU(N_c)$ gauge theory"

$$\Sigma_{SW} \quad \omega + \frac{\Lambda^{2N_c}}{\omega} = P_{N_c}(x, u)$$

$$\lambda_{SW}(u) = \frac{1}{2\sqrt{2}\pi} x(\omega, u) \frac{d\omega}{\omega}$$

$$P_{N_c}(x, u) = \det(x \mathbf{1} - \langle \phi \rangle) = x^{N_c} - \sum_{k=0}^{N_c-1} u_k x^k$$

But we have also seen identical algebraic curve before, this is precisely the so-called "Spectral Curve" for A_{N-1} Toda-System (Classical)

- Or for our prototype $N=2$ Super-QCD, the Seiberg-Witten curve Σ_{sw} is given by (Argyres, Plesser, Shapere)

$$\Sigma_{sw} \quad \omega^2 \prod_{\ell=1}^{N_c} (x - \tilde{m}_\ell) - 2\omega \prod_{\ell=1}^{N_c} (x - a_\ell) - h(h+2) \prod_{\ell=1}^{N_c} (x - m_\ell) = 0$$

$$h = -\frac{2q}{1+q}, \quad q = e^{2\pi i \tau} \rightsquigarrow \text{Instanton correction}$$

Again, we have seen similar algebraic curve in "Classical integrable system", this is the spectral curve for "inhomogeneous twisted XXX spin chain"

$$P(z) = 2 \prod_{\ell=1}^{N_c} (z - \phi_\ell)$$

$$\Sigma_{xxx} \quad t^2 - 2P(z)t + h(h+2)K_+(z)K_-(z) = 0$$

$$K_{\pm}(z) = \prod_{\ell=1}^{N_c} (z - \theta_{\ell \pm}, J_\ell)$$

Indeed, we can identify $(a_I(u), a_I^D(u))$ with **Canonical Coord** from H_{XXX} , also $\langle \text{Tr} \phi^k \rangle$ with **Commuting Conserved Charges**.

- So far we have discussed how 4 dim SUSY gauge theories can be related to **Classical Integrable Systems**, but can we also see **"Quantum Integrable Systems"** emerge from 4 dim theories?

- To quantize a dynamical system, we need to identify **Appropriate Vacuum**, in our XXX spin chain, we can start with **"Ferromagnetic Vacuum"**

- In SQCD, after we identify the parameters in gauge theory and integrable spin chain, this precisely corresponds to

"Root of Baryonic Higgs"

$$a_l - M_l = 0, \quad l=1, \dots, N_c$$

Q. What about "Planck Constant \hbar " for quantization?

A. Nekrasov and Shatashvili proposed a striking idea, that is to put 4dim $N=2$ gauge theories on "Curved Background", or a "topologically twisted version" (Coupling spacetime with internal symmetries)

More Concretely, We consider the Euclidean Rotational Group

$$\mathbb{R}^4 \simeq \mathbb{C} \times \mathbb{C} \quad U(1)_1 \times U(1)_2 \subset SO(4) \simeq SU(2)_1 \times SU(2)_2$$

and break the rotational symmetry in two out of four directions, with the deformation parameter " ϵ " $((z_1, z_2) \rightarrow (z_1, e^{i2\pi\epsilon} z_2))$

- Both Rotational Symmetry and Supersymmetry are partially Broken Only preserved in $\mathcal{X}^1 - \mathcal{X}^2$ plane, $N=(2,2)$ in 2 dimensions "Notice that this is however different $N=(2,2)$ theory from earlier discussion"

- The proposal of **Nekrasov-Shatashvili** is that, in such deformed $\mathcal{N}=2$ theory, if we compute **the prepotential** $F(\vec{a}, \vec{m}, \epsilon)$

("Kinetic term $\sim \text{Im} \left(\frac{\partial F}{\partial \vec{a}} \vec{a} \right)$, gauge coupling $\tau \sim \partial_{\vec{a}}^2 F$)

- Proposal $F(\vec{a}, \vec{m}, \epsilon)$ is the **Yang-Yang functional** of the for quantizing the underlying **Classical integrable system** That is

$$\frac{1}{2\pi i} \frac{\partial F(\vec{a}, \vec{m}, \epsilon)}{\partial \vec{a}} = \vec{n} \epsilon \quad \sim \epsilon \text{ Planck constant } \hbar$$

- From perspective of Σ_{SW} , $\frac{\partial F}{\partial \vec{a}}$ can be identified with the

β -Cycle / dual cycle of \vec{a} \rightsquigarrow We are quantizing "Canonical Momentum"

- Many possible Choices of **Quantizations**, they are related via **"Electromagnetic Duality Transformation"**

- After long detour in 4 dim, let us recall in the original 2-dim theory, the BAE arises from "Standard quantization condition" in algebraic ansatz equation That is "quantizing around Ferromagnetic Vacua"

$$\vec{a} - \vec{m} = \vec{n} \epsilon \sim \text{identification of } \hbar \sim \epsilon$$

- Proposal (Chen et al, also CDL)

Partition of flux tubes

$$F(\vec{a} = \vec{m} - \vec{n} \epsilon) - F(\vec{a} = \vec{m} - \epsilon \hat{1}) = W(\vec{n})$$

Vacuum - dependent

Proved in (Chen et al)

Can be argued from both "Identical Quantization Condition"

+

The minima obtained from the potentials in 2 dim and 4 dim Gauge theories both coincide with eigenstates of H_{xxx}

Brane Construction for 2d/4d Duality

/// ~ "vortices"

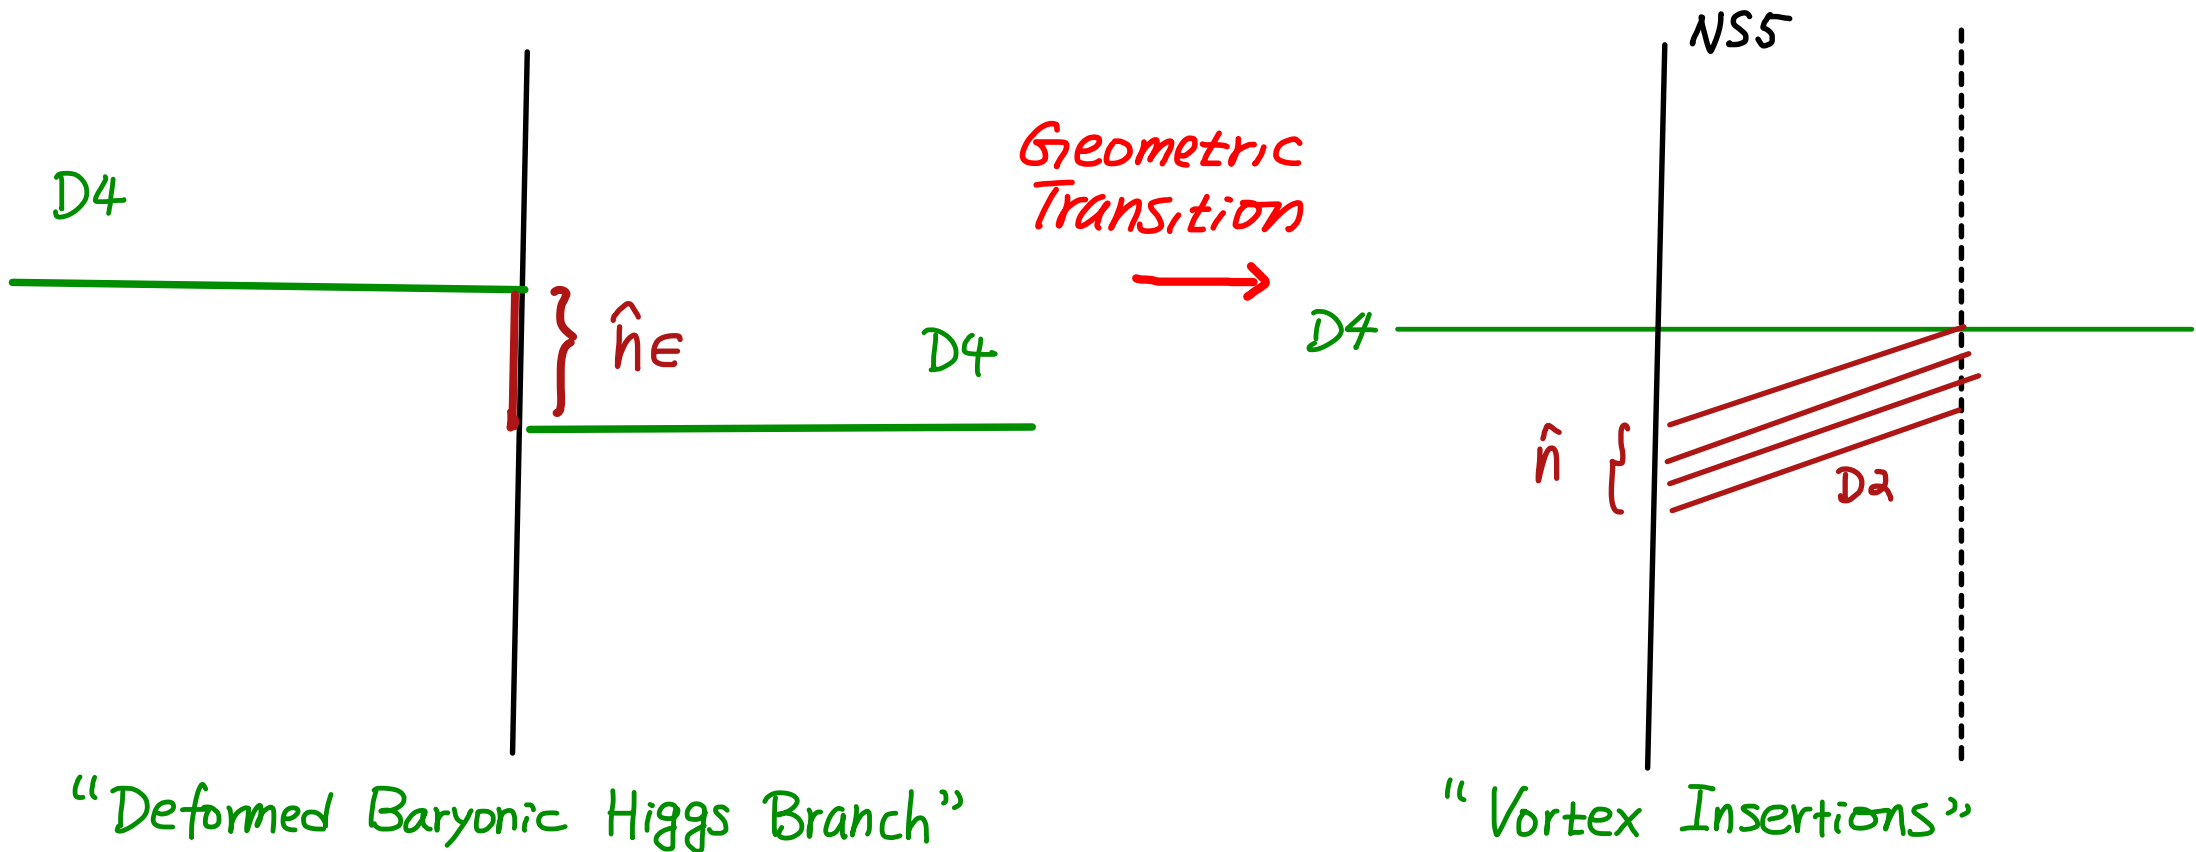

$N=(2,2)$ GLSM appears as world volume theory

- More Intuitive Explanation (HYC + Annamaria Sinkovics)
 "2d SUSY GLSM is the Vortex World Volume Theory of the dual 4d SUSY Theory"

Probing Specific 4d Vacua Baryonic Higgs Root

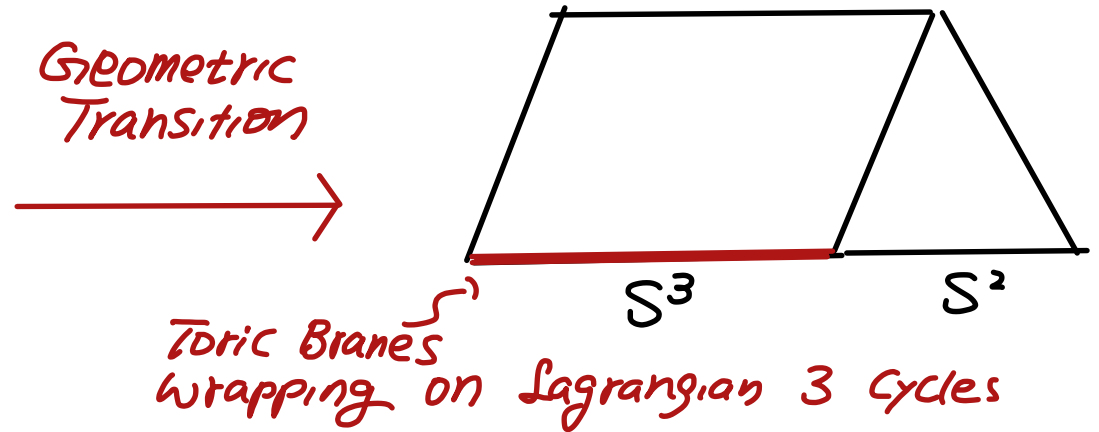

D-brane Pictures

This is in fact a realization of "Geometric Transition"

"Resolved Conifold"

"Deformed Conifold"

This picture allows to construct many other "Duality Pairs",
Connecting Geometric Transition with Integrable Structures in
Supersymmetric Gauge Theories (HYC + Annamaria Sinkovics)
